

Social Media Security

Distributed Systems

Introduction

This distributed application is designed to analyze the social media security of our users. They can analyze which is the personal information that they make public in their social media accounts. Specifically, they can analyze their Facebook and Twitter accounts. The objective is raise awareness among users that they can put a lot of personal information public, and this can be a risk because the hackers can use social engineering to condition their ideologies or decisions. Even thieves can take advantage of this information to find out where you live and rob your home if you are on holidays.

This software implements serverless architecture and use IBM Cloud Functions to execute this app. Also, we used Lithops API to execute IBM Cloud Functions and store user's data in IBM Object Storage. Therefore, we use an object-oriented storage architecture.

Now, let's analyze the information produced by our application. We used the Hillary Clinton, Barack Obama and Mufti Menk (Imam) profiles to generate the analyzed data.
